How to install ssl certs in jump server [secure connection]?

207 Manu Chacko October 10, 2025 Tweaks & Configuration 15419

How to Create a SSL Certificate on jump server Apache for Ubuntu 20/ Ubuntu 22/Ubuntu 24/ Debian12/ Debian11 ?

Step 1. Install Apache2

root@gateway:~# apt-get install apache2

Step 2. Create a New Directory

We need to create a new directory where we will store the server key and certificate

root@gateway:~# mkdir /etc/certs/ssl

Step 3. Create a Self Signed Certificate

When we request a new certificate, we can specify how long the certificate should remain valid by changing the 365 to the number of days we prefer. As it stands this certificate will expire after one year.

root@gateway:~# openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout /etc/ssl/private/apache-selfsigned.key -out /etc/ssl/certs/apache-selfsigned.crt

With this command, we will be both creating the self-signed SSL certificate and the server key that protects it, and placing both of them into the new directory.

This command will prompt terminal to display a lists of fields that need to be filled in.

You are about to be asked to enter information that will be incorporated into your certificate request.

What you are about to enter is what is called a Distinguished Name or a DN.

There are quite a few fields but you can leave some blank

For some fields there will be a default value, If you enter '.', the field will be left blank.

Country Name (2 letter code) [AU]:US

State or Province Name (full name) [Some-State] :New York

Locality Name (eg, city) []:NYC

Organization Name (eg, company) [Internet Widgits Pty Ltd] :Awesome Inc

Organizational Unit Name (eg, section) [] :Dept of Merriment

Common Name (e.g. server FQDN or YOUR name) []:example.com

Email Address []:webmaster@awesomeinc.com

Step 4. Modify the Default Apache SSL Virtual Host File.
Let's modify /etc/apache2/sites-available/default-ssl.conf default Apache SSL Virtual Host file.
Before we go any further, let's back up the original SSL Virtual Host file:
root@gateway:~# cp /etc/apache2/sites-available/default-ssl.conf /etc/apache2/sites-available/default-ssl.conf.bak
Now, open the SSL Virtual Host file to make adjustments:
root@gateway:~# nano /etc/apache2/sites-available/default-ssl.conf
Find the section that begins with <virtualhost _default_:443=""> and Uncomment the DocumentRoot and ServerName line and replace example.com with your domain name or server IP address. Also uncomment SSLCertificateFile, SSLCertificateKeyFile, SSLEngine on & add the correct path of cert file & key file.</virtualhost>
DocumentRoot and ServerName line and replace example.com with your domain name or server IP address. Also uncomment SSLCertificateFile, SSLCertificateKeyFile,
DocumentRoot and ServerName line and replace example.com with your domain name or server IP address. Also uncomment SSLCertificateFile, SSLCertificateKeyFile,
DocumentRoot and ServerName line and replace example.com with your domain name or server IP address. Also uncomment SSLCertificateFile, SSLCertificateKeyFile,
DocumentRoot and ServerName line and replace example.com with your domain name or server IP address. Also uncomment SSLCertificateFile, SSLCertificateKeyFile,
DocumentRoot and ServerName line and replace example.com with your domain name or server IP address. Also uncomment SSLCertificateFile, SSLCertificateKeyFile,

```
<IfModule mod_ssl.c>
<VirtualHost _default_:443>
ServerAdmin your_email@example.com
ServerName server_domain_or_IP
DocumentRoot /var/www/html
ErrorLog ${APACHE_LOG_DIR}/error.log
CustomLog ${APACHE_LOG_DIR}/access.log combined
SSLEngine on
SSLCertificateFile
                    /etc/ssl/certs/apache-selfsigned.crt
SSLCertificateKeyFile /etc/ssl/private/apache-selfsigned.key
<FilesMatch ".(cgilshtmllphtmllphp)$">
SSLOptions +StdEnvVars
</FilesMatch>
<Directory /usr/lib/cgi-bin>
SSLOptions +StdEnvVars
</Directory>
BrowserMatch "MSIE [2-6]"
nokeepalive ssl-unclean-shutdown
downgrade-1.0 force-response-1.0
```

Save & Exit the file.
Step 5. Enable the Changes in Apache
root@gateway:~# a2enmod ssl
root@gateway:~# a2ensite default-ssl
Also <u>enforce ssl</u> in ezeelogin gui.
Restart Apache
root@gateway:~# systemctl restart apache2

How to Create a SSL Certificate on ezeelogin jump server Apache for Almalinux 9/ Almalinux 8/ Rocky Linux 9/ Rocky Linux 8?

Overview: This article covers creating SSL certificates on Ezeelogin jump servers by installing necessary packages, creating directories for storing keys and certificates, generating self-signed certificates, and configuring Apache virtual hosts. This ensures secure HTTPS connections on CentOS and Ubuntu/Debian systems.

Step 1. Install Mod SSL

root@gateway:~# yum install mod_ssl openssl

Step 2. Create a New Directory

We need to create a new directory where we will store the server key and certificate

root@gateway:~# mkdir /etc/httpd/ssl

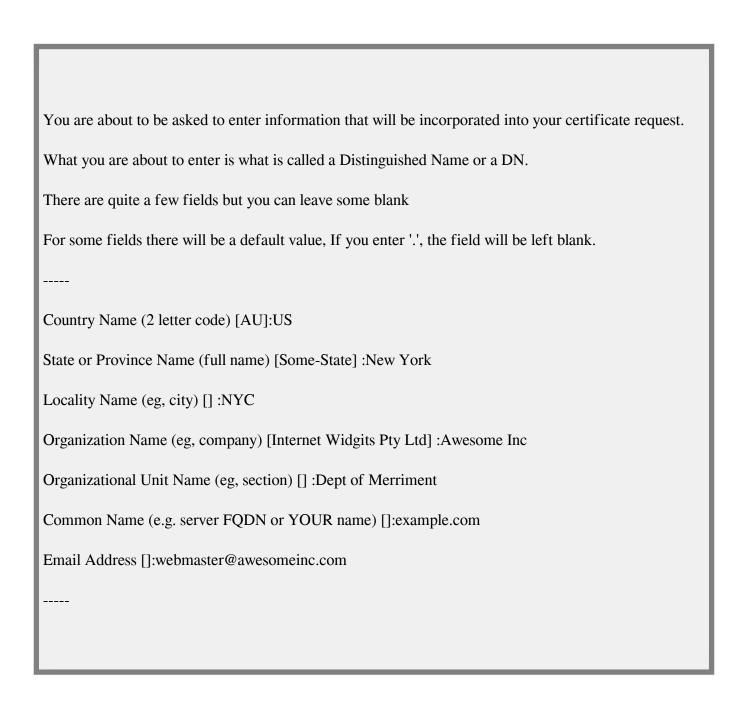

Step 3. Create a Self Signed Certificate

When we request a new certificate, we can specify how long the certificate should remain valid by changing the 365 to the number of days we prefer. As it stands this certificate will expire after one year.

root@gateway:~# openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout /etc/httpd/ssl/apache.key -out /etc/httpd/ssl/apache.crt

With this command, we will be both creating the self-signed SSL certificate and the server key that protects it, and placing both of them into the new directory.

This command will prompt terminal to display a lists of fields that need to be filled in.

Step 4. Set up the virtual hosts to display the new certificate.

Your virtual host is now all set up! Save and Exit.

Restart Apache

root@gateway:~# systemctl restart httpd
