How to configure Ezeelogin to automatically discover and import servers on a scheduled basis with automatic creation of managed SubSSH users?

Overview: This guide provides step-by-step instructions for configuring Ezeelogin to automatically discover and import servers on a scheduled basis. By specifying an IP range or CIDR block, Ezeelogin can identify available servers and automatically add them to the gateway. The discovery process is performed by an auto discovery script that runs at scheduled intervals using a cron job.

This feature is available starting from Ezeelogin version 7.47.0. Refer article to [upgrade Ezeelogin to latest version](#).

Step 1: Enable API options from Ezeelogin GUI

Navigate to the **Servers tab** and click **API**. Enable both the **Enable API** and **Server API** options. Refer below screenshot.

Step 2: Create a CSV file to import or manually add IP range/CIDR block in GUI

Method 1: Create an IP Range or CIDR Block manually. Provide a name for the entry, specify the **IP range or CIDR block**, and enter the **SSH port**, **username**, and **password** that will be used to connect to the servers within the specified range.

Note: All remote servers within the specified IP range or CIDR block must use the same SSH port, username, and password. Ezeelogin will use these credentials during the discovery process to connect to and add the relevant servers.

	prod-servers	192.168.56.102-111	production servers	

1 - 1 / 1

Method 1.a: Create a CSV with below details:

name	ips	description	port	user	password	keep_password	servergroup
prod_server_1	192.168.56.100	prod_server_1	22	root	password123	S	production servers
prod_server_2	192.168.56.101	prod_server_1	22	root	password123	S	production servers
prod_server_3	192.168.56.102	prod_server_1	22	root	password123	S	production servers

Method 1.b: Upload the CSV file through the GUI and **import** it to populate the **Auto Discover** tab with the listed servers. Note that this process only imports the server entries into the Auto-Discover tab and does not create valid servers in Ezeelogin.

prod_server_16	192.168.56.115	production servers	22	prod_server_16
prod_server_17	192.168.56.116	production servers	22	prod_server_17
prod_server_18	192.168.56.117	production servers	22	prod_server_18
prod_server_19	192.168.56.118	production servers	22	prod_server_19
prod_server_2	192.168.56.101	production servers	22	prod_server_2
prod_server_20	192.168.56.119	production servers	22	prod_server_20

Step 3: Configure a Cron Job to Run the Auto Discovery Script on a Scheduled Basis

To automate server discovery, **configure a cron job to run the auto discovery script at regular intervals** based on the requirements (daily, weekly, or monthly).

```
root@gateway:~# crontab -e
```

Add one of the following entries:

Daily (at 1:00 AM every day):

0 1 * * * php /usr/local/ezlogin/auto_discovery.php

Weekly (at 1:00 AM every Sunday):

0 1 * * 0 php /usr/local/ezlogin/auto_discovery.php

Monthly (at 1:00 AM on the first day of every month) :

0 1 1 * * php /usr/local/ezlogin/auto_discovery.php

After saving the crontab, verify that the entry has been added successfully:

```
root@gateway:~# crontab -l
```

The configured cron job will automatically execute the auto discovery script at the scheduled time, allowing Ezeelogin to discover and import eligible servers from the configured IP ranges or CIDR blocks without manual intervention.

Step 4: How to run the script manually and auto-import available servers?

In this example, Ezeelogin will attempt to connect via SSH to all servers within the IP range 192.168.56.102 to 192.168.56.111. If Ezeelogin successfully establishes an SSH connection to a server, the server will be automatically added to Ezeelogin. Servers that cannot be reached or authenticated via SSH will not be added. Once a server has been successfully added, Ezeelogin will automatically create all managed SubSSH users on the newly added server.

Run the below command on gateway server:

```
root@gateway:~# php /usr/local/ezlogin/auto_discovery.php
```

```
root@gateway-server:~# php /usr/local/ezlogin/auto_discovery.php
Discovery profile: prod-servers (192.168.56.102-111)
192.168.56.103 (ubuntu1): added
192.168.56.103 (ubuntu1): sub SSH users setup initiated
192.168.56.106 (ubuntu2): added
192.168.56.106 (ubuntu2): sub SSH users setup initiated
192.168.56.107 (ubuntu3): added
192.168.56.107 (ubuntu3): sub SSH users setup initiated
Done: 10 scanned, 3 online, 3 added
root@gateway-server:~#
```

Step 5: How to view the added servers?

Navigate to the **Servers tab** and **refresh the browser**. Auto discovered servers will be listed along with the description configured for the auto discovery profile.

Common Questions and Errors During Auto Discovery

Q1. Why is the scanned count different from the total count of servers in the CSV file or the IP range/CIDR block?

```
root@gateway-server:~# php /usr/local/ezlogin/auto_discovery.php
Discovery profile: prod-servers (192.168.56.102-111)
Done: 7 scanned, 0 online, 0 added
root@gateway-server:~#
```

Answer: The scanned count may differ from the total number of IP addresses in the CSV file or IP range/CIDR block because it only includes servers that Ezeelogin actually attempts to scan. IP addresses that already exist in Ezeelogin are skipped during the scan, and therefore are not included in the scanned count. As a result, the scanned count reflects only the new or unregistered servers that are evaluated during the auto discovery process, not the total number of IP addresses in the specified range.

Error 1: add_server failed [{"name":"The server exists"}]

```
root@ubuntu1:~# php /usr/local/ezlogin/auto_discovery.php
Discovery profile: prod-servers (192.168.56.102-111)
192.168.56.103 (ubuntu1): added
192.168.56.103 (ubuntu1): sub SSH users setup initiated
192.168.56.106 (ubuntu3): added
192.168.56.106 (ubuntu3): sub SSH users setup initiated
192.168.56.107 (ubuntu3): add_server failed [{"name":"The server exists"}]
Done: 10 scanned, 3 online, 2 added
root@ubuntu1:~#
root@ubuntu1:~#
```

Answer: This is because another server has already been added to Ezeelogin with the same hostname. In this example, the hostname **ubuntu3** is already associated with a different IP address in Ezeelogin, preventing the newly discovered server from being added with the same hostname.
